

Introduction

- Higher body weight individuals are frequently the targets of negative weight-based stereotypes (e.g., unintelligent, lazy) and prejudicial attitudes.
- According to Allport (1954), prejudice is unlikely to be a specific attitude toward a specific group, but rather is likely to be a general way of thinking about the world.
- Workplace discrimination harms the economic, psychological, and physical well-being of larger individuals by increasing their stress levels and reducing their chances of being hired or promoted.

Present Study

We hypothesized that differences in body size would affect competence-based judgements of female "employees," and further that participant's personality traits and social attitudes would influence these judgements.

Methods

College students (N = 161) from a northeastern university were recruited to participate in this study, and the study took place entirely online.

Sample

- Participants were mostly female (60.9%), and identified as White (45.3%), Black (29.8%), Hispanic (18.0%), Asian (9.3%), and other (3.7%).
- The average BMI was 25.40 (SD = 5.06) and the average age was 20.64 years (*SD* = 3.29).

Measures

- Participants responded to 12 images of 3 identically dressed women of varying body sizes (found in a pilot test to be perceived as "normal weight," "overweight," and "obese").
- The images were rated using a 6-item global competence measure (Howelett et al., 2015).
- Participants also completed the Antifat Attitudes scale (Dislike subscale; Crandall, 1994), the Need for Cognitive Closure scale (NFC, Roets et al., 2015), and the Essentialist Entitativity scale (EE, altered to be weight specific, adapted by Roets & Van Hiel, 2011).
- Participants were also asked what they believed the study was about.

Weight Bias in the Workplace: Does Personality Matter?

Jamie Price Dunaev, Trista N. Harig, Caitlyn Kliniewski, Robert Hughes, German Laverde, Charlotte H. Markey Rutgers University-Camden

Higher body weight individuals are judged as being less competent when compared to lower body weight individuals, even when participants know the purpose of the study.

Repeated Measures ANOVA: F(2,158) = 26.53, p < .001, $\eta^2 = 0.14$ The "obese" employee was rated as significantly less competent when compared to the "normal weight" (t(160) = 6.12, p < .001, d = 0.55) and "overweight" (t(160) = 6.05, p < .001, d = 0.48) targets.

Results

Error bars: 95% Cl

- competence. that:
 - Need for Cognitive Closure had a small significant effect (F(2, 158) = 3.88, p = .022, $\eta^2 = .02$
 - on competence ratings (F(2, 158) = 1.26,
 - Antifat Attitudes had small non-significant effect $p = .286, \eta^2 = .01)$
 - Essentialist Entitativity beliefs had a small nonsignificant effect on competence ratings
 - $(F(2, 158) = 2.26, p = .108, \eta^2 = .02)$
- sizes.
- attitudes.

Results

Most participants (82%) reported believing the study was about weight/physical appearance and how that influences judgments of work ability or

Using Repeated Measures ANCOVAs, we found

Discussion

 Individuals with larger body sizes were deemed to be less competent than individuals with smaller body

 These results held despite participants clearly understanding the purpose of the study, suggesting the social acceptability of negative weight-based

 Our study further suggests that competence ratings are minimally influenced by an individuals' personality characteristics, particularly their need for cognitive closure. In other words, negative weightbased attitudes may fulfill an individuals' need for disambiguation and quick judgements.

• There may a threshold at which individuals begin to judge others negatively based on their body size. Future research should continue to examine body size as existing on a continuum.
